Aeromancy: Towards More Reproducible AI and Machine Learning

David McClosky QuantAQ Inc.

On reproducibility

O Goal: Make it easy to **replicate** or **modify** any existing experiment

- **L** Reproducible experiments are critical for good science, aid debugging, and clarify data lineage
- **Data pipelines and ML experiments** are **not reproducible** by default
- Code depends on full environment (OS, compilers, libraries, etc.)
- **Datasets and models** are often unversioned, can change frequently
- **T** Existing **Experiment Managers** (e.g., Weights and Biases, MLFlow) track many, but not all of these details

Aeromancy has opinions

Runtime Container

 $\Rightarrow \aleph_{0} \otimes git$ commit hash <>Code $\rightarrow \stackrel{\bullet}{\longrightarrow}$ docker. base image \blacksquare Libraries $] \rightarrow \bigcirc$ Debian package versions **External Artifacts** $\rightarrow \bigcirc$ S3-like Object Storage 🖽 Data

- Code **must** be checked in, clean repo Data must be immutable, versioned
- Environment **must** be a container
- Experiments can't run in **notebooks** (but read on...)

Aeromancy's stack

- Left Aeromancy wraps Weights & Biases
- Data stored in S3-like blobstore (e.g., <u> ceph</u>)
- Version control by
- Virtual environments by OPDM

Want reproducible data pipelines and machine learning?

Track your whole environment, not just your code.

Take a picture to see Aeromancy on GitHub: https://github.com/quant-aq/aeromancy

Fully tracked in Aeromancy

Versions are nested

• One version to track them all:

Experiment version

Expt. Metadata

commit hash Data artifacts

$\downarrow \downarrow \downarrow \downarrow$ **Object Storage**

♀model3 v1 🖹 dataset2 v4 🖬 dataset7 v3

Git Repository

<>Code

- ➡ pyproject.toml (incl. 🖐 docker. flags & system packages)
- **Python library** versions

Docker details

- Record system package versions while building container
- Support hooks for installing system packages, custom Docker flags
- Optimized for fast rebuilds
- Special data/ folder for dataset **ingestion** (once per external dataset)

Reducing friction

- **Provide a command** to rebuild container and launch experiments
- **dev mode** allows fast, offline iteration outside of containers (untracked)
- **Cache data artifacts** locally to save network traffic (deduplicated by hash)
- **C** Rerun existing experiments with a single command

What about notebooks?

- Flexibility in notebooks makes it tough to fully track them
- **Tracking notebooks requires backend** support or **disciplined** use
- Still great for analysis and plots, so Aeromancy provides tools to **import** data/models in notebooks

Future work

- **Expand integrations** (e.g., MLFlow)
- **Directly integrate into Experiment** Managers
- Wake it trivial to **self-host** object storage and connect with Aeromancy
